A differential equation is an equation which contains one or more terms which involve the derivatives of one variable (i.e., dependent variable) with respect to the other variable (i.e., independent variable).  $dy/dx = f(x)$  Here "x" is an independent variable and "y" is a dependent variable. For example,  $dy/dx = 5x$ . A differential equation that contains derivatives which are either ...

We don't know values for the parameters  $b$  and  $k$  yet, but we can estimate them, and then adjust them as necessary to fit the excess death data. We have already estimated the average period of infectiousness at three days, so that would suggest  $k = 1/3$ . If we guess that each infected would make a possibly infecting contact every two days, then  $b$  would be  $1/2$ .
