Chromosomes, Genes, and Cell Division Flashcards - Quizlet

Genes are contained in chromosomes, which are mainly in the cell nucleus. A chromosome contains hundreds to thousands of genes. Every human cell contains 23 pairs of chromosomes, for a total of 46 chromosomes. A trait is any gene-determined characteristic and is often determined by more than one gene.

Simply defined, a chromosome is a cell that, has shown in the picture above, contains protein and one DNA molecule that is found in the nucleus of the cell. Nucleotides are the basic cells that serve as the building blocks of both RNA and DNA.

What is a gene? - Genetics Home Reference - NIH

The genetic material of each cell is packaged together in the nucleus as chromosomes and each one of these contains very long DNA molecules. The human body has 46 chromosomes and in each body cell the chromosomes are in pairs, called homologous and a full set of chromosomes is called the karyotype.

Difference between DNA, Genes and Chromosomes - Explainry

Genes occur in a linear sequence along a chromosome and a single chromosome may contain hundreds of genes. Because chromosomes occur in pairs, genes also occur in pairs. An inherited trait is determined by at least one pair of genes.

Chromosomes are structures that cells use to organize their DNA for cell division. Chromosomes typically contain thousands of genes, written in DNA. Since there are exceptions to just about every rule in biology, there are a few situations where genes are written in something other than DNA, like the RNA of viruses and the proteins of prions, but none of these are universally regarded as alive.
