The microbes then dislodge and uniquely break down the trapped oil within the pore spaces into smaller droplets which can be recovered more efficiently. This oleophilic activity is an entirely new direction in the field of enhanced oil recovery. This process is simple, efficient, inexpensive and 100% environmentally friendly.

Enhanced-Oil Recovery (EOR) for asset acquisition or rejuvenation involves intertwined decisions. In this sense, EOR operations are tied to a perception of high investments that demand EOR workflows with screening procedures, simulation and detailed economic evaluations.

Enhanced oil recovery, also called tertiary recovery, is the extraction of crude oil from an oil field that cannot be extracted otherwise. EOR can extract 30% to 60% or more of a reservoir's oil, compared to 20% to 40% using primary and secondary recovery. According to the US Department of Energy, there are three primary techniques for EOR: thermal, gas injection, and chemical injection. More advanced, speculative EOR techniques are sometimes called quaternary recovery.

displacement causes the intermediate component in the gas to condense into the equilibrium oil, causing the trapped oil to swell, which helps recovery. This process is known as a condensing drive, where miscibility is developed at the trailing edge of the displacements by backward contacts.

Enhanced-Oil Recovery (EOR) evaluations focused on asset acquisition or rejuvenation involve a combination of complex decisions, using different data sources. EOR projects have been traditionally associated with high CAPEX and OPEX, as well as high financial risk, which tend to limit the number of EOR projects launched.
